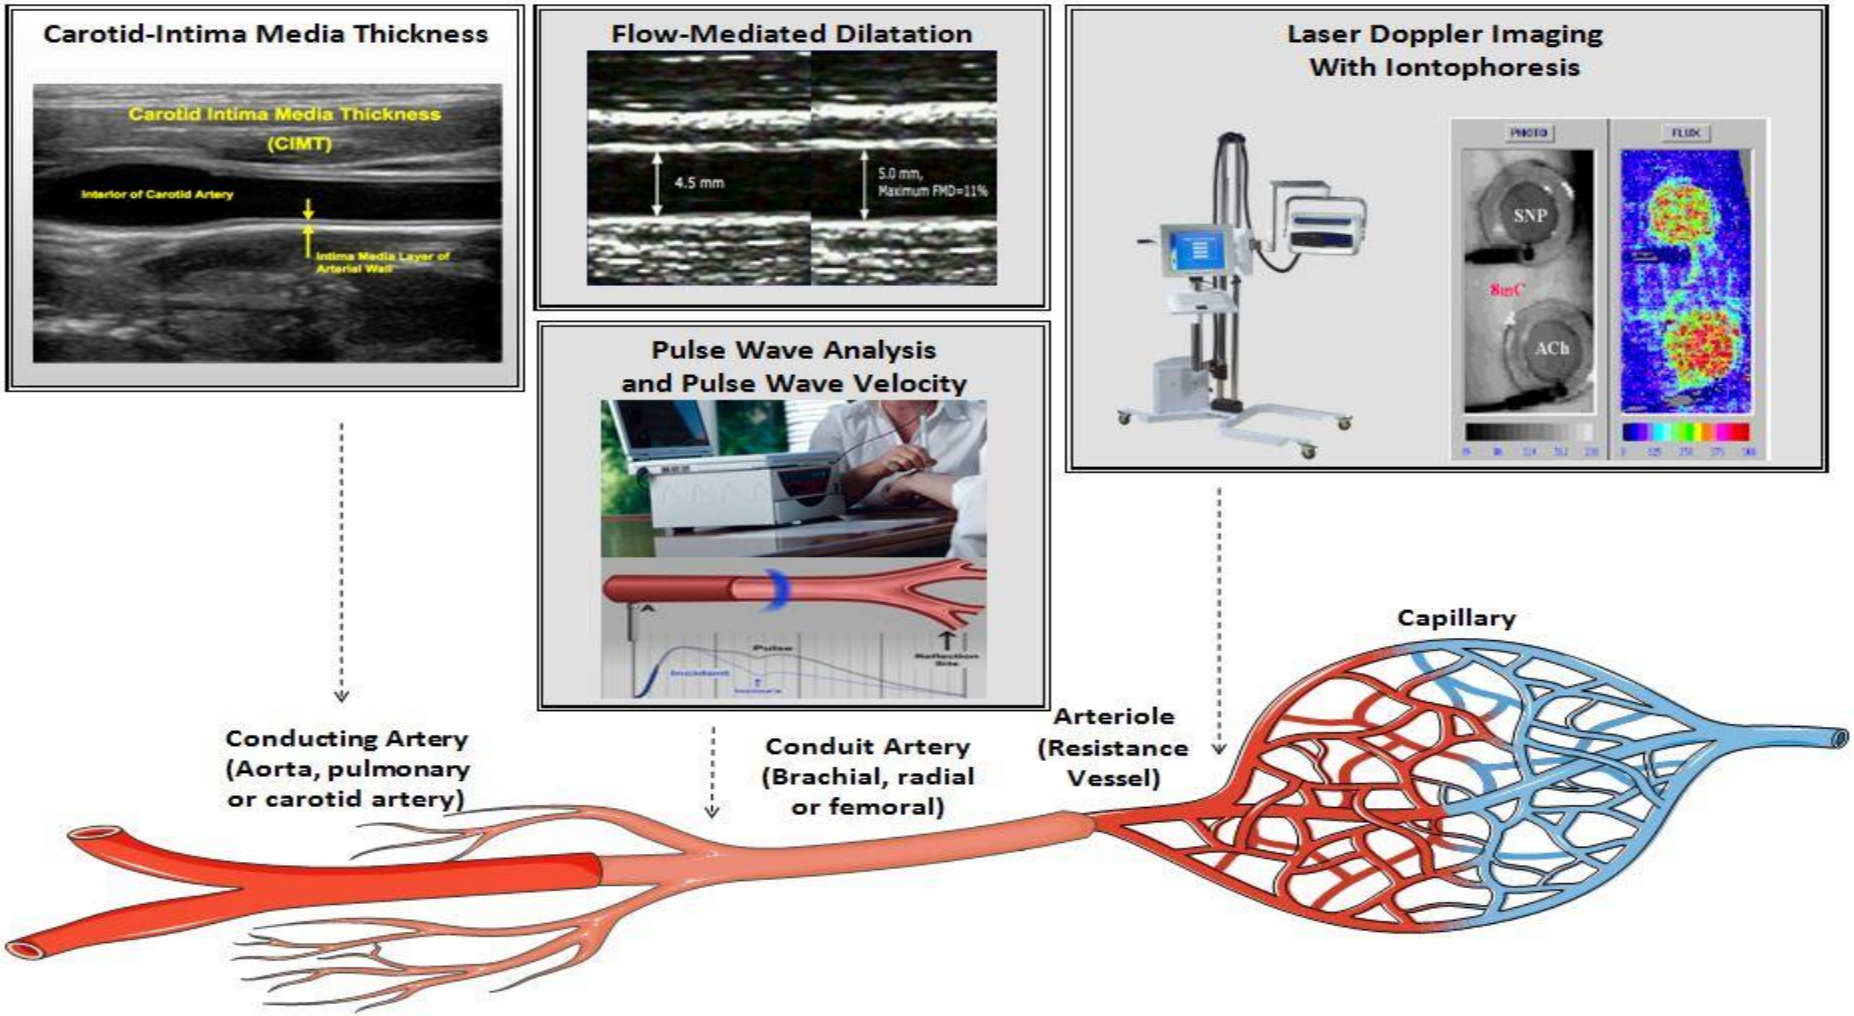
Sub-clinical atherosclerosis: Non-invasive vascular assessments



Are they good surrogates of future CVD events in RA?

Sandoo et al: Rheumatology 2011

Summary – Vascular function and morphology in RA:

- Sub-clinical atherosclerosis appears to be more pronounced in RA compared to controls – equal to Type 2 DM
- Classical CVD risk factors appear to have a greater impact than systemic inflammation on most vascular parameters
- Changes in microvascular and macrovascular endothelial function are independent of each other
- Classical CVD risk factors and inflammation have different effects on vascular smooth muscle cells and endothelial cells

What is the evidence for (accelerated) atherosclerosis in RA?

- Theory: the role of inflammation
- Vascular function and morphology studies - biomarkers
  (sub-clinical atherosclerosis)
- Epidemiology: **RA = DM type 2**
  (DM type 2 = CHD equivalent)

CVD morbidity in RA = DM

The Impact of Inflammation on Metabolomic Profiles in Patients With Arthritis

Stephen P. Young,[1] Sabrina R. Kapoor,[2] Mark R. Viant,[1] Jonathan J. Byrne,[1] Andrew Filer,[3] Christopher D. Buckley,[2] George D. Kitas,[4] and Karim Raza[2]

Objective. **Inflammatory arthritis is associated with systemic manifestations including alterations in metabolism. We used nuclear magnetic resonance (NMR) spectroscopy–based metabolomics to assess metabolic fingerprints in serum from patients with established rheumatoid arthritis (RA) and those with early arthritis.**

Methods. **Serum samples were collected from newly presenting patients with established RA who were naive for disease-modifying antirheumatic drugs, matched healthy controls, and 2 groups of patients with synovitis of ≤3 months' duration whose outcomes were determined at clinical followup. Serum metabolomic profiles were assessed using 1-dimensional ^{1}H-NMR spectroscopy. Discriminating metabolites were identified, and the relationships between metabolomic profiles and clinical variables including outcomes were examined.**

Results. **The serum metabolic fingerprint in established RA was clearly distinct from that of healthy controls. In early arthritis, we were able to stratify the patients according to the level of current inflammation, with C-reactive protein correlating with metabolic differences in 2 separate groups ($P < 0.001$). Lactate and lipids were important discriminators of inflammatory burden in both early arthritis patient groups. The sensitivities and specificities of models to predict the development of either RA or persistent arthritis in patients with early arthritis were low.**

Conclusion. **The metabolic fingerprint reflects inflammatory disease activity in patients with synovitis, demonstrating that underlying inflammatory processes drive significant changes in metabolism that can be measured in the peripheral blood. The identification of metabolic alterations may provide insights into disease mechanisms operating in patients with inflammatory arthritis.**

The etiology of rheumatoid arthritis (RA) is not fully understood but involves both genetic and environmental factors. In addition to synovitis, there are widespread systemic effects mediated by proinflammatory cytokines that impact on metabolism. Tumor necrosis factor α, interleukin-1 (IL-1), and IL-6 all promote

Dr. Kapoor's work was supported by an Arthritis Research UK Clinical PhD Studentship (grant 18552). The nuclear magnetic resonance data were acquired at the Henry Wellcome Building for Biomolecular Nuclear Magnetic Resonance Spectroscopy at the University of Birmingham; the facility is funded by the Wellcome Trust (grant 066490/Z/01/A).

Lipid metabolites “low” in very early, active or persistent inflammatory arthritis…

Table 2. Metabolites contributing to the differentiation between groups, determined by analysis of PLS-DA weightings*

Metabolite, ppm	RA patients versus controls	Patients with early arthritis before versus after resolution of inflammation	Patients with persistent arthritis versus patients with resolving arthritis (group 1)	Patients with persistent arthritis versus patients with resolving arthritis (group 2)	Patients with persistent RA versus patients with resolving arthritis (group 1)	Patients with persistent RA versus patients with resolving arthritis (group 2)
LDL-CH3, 0.80	Low (6.30)	Low (3.03)	Low (6.81)	Low (2.87)	–	–
LDL-CH2, 1.21	Low (7.06)	Low (31.81)	Low (7.40)	Low (6.89)	–	Low (1.58)
3-hydroxybutyrate, 1.18, 1.19	High (4.21)	High (7.90)	–	High (6.87)	–	–
Lactate, 1.31, 4.11	High (54.51)	–	Low (12.85)	High (27.90)	Low (12.74)	High (16.98)
Alanine, 1.46, 1.48	Low (20.00)	Low (2.15)	–	–	–	Low (3.84)
Acetylglycine, 2.03	High (48.67)	High (17.41)	High (6.55)	High (6.80)	High (4.57)	Low (1.94)
Methylguanidine, 2.81	Low (10.17)	–	High (92.72)	Low (38.15)	High (34.76)	Low (6.51)
Taurine, 3.26	High (8.12)	High (9.11)	–	High (15.73)	–	High (8.66)
Glucose, 3.25, 3.88	High (16.8)	High (12.72)	–	High (11.55)	–	High (7.49)
Lipid, 5.32	Low (2.36)	Low (2.53)	–	–	–	–
Urea, 5.79	–	High (1.32)	High (3.90)	–	High (1.25)	–

*“High” indicates that the metabolite was at a higher concentration in the rheumatoid arthritis (RA; column 2), early arthritis before resolution (column 3), persistent arthritis (columns 4 and 5), or persistent RA (columns 6 and 7) phenotypes. Nuclear magnetic resonance chemical shifts (in parts per million), which identify the location of the major peaks in the spectra, are shown for each metabolite. Values in parentheses are the variable importance of the projection for each metabolite. PLS-DA = partial least-squares discriminant analysis; LDL-CH3 = low-density lipoprotein CH3.

…and correlate with CRP…

Table 3. Metabolites most strongly correlated with CRP level in patients with early arthritis in groups 1 and 2*

Ranked importance	Metabolites identified in patient group 1 (ppm)	Metabolites identified in patient group 2 (ppm)
1	Choline (3.20, 3.22, 3.23)	LDL lipids (1.24–1.27)
2	LDL lipids (1.24–1.27)	Acetylglycine (2.03, 3.71, 3.76)
3	Lactate (1.31, 1.33, 4.11)	Glucose (3.24–3.26, 3.41, 3.48, 3.68–3.69, 3.88)
4	Acetylglycine (2.03, 3.71, 3.76)	Fatty acids (0.8–0.84, 2.22–2.24)
5	Urea (5.77, 5.78, 5.79, 5.80, 5.81, 5.82)	Methylguanidine (2.81)
6	Glucose (3.24–3.26, 3.41, 3.48, 3.68–3.69, 3.88)	Lactate (1.31, 1.33)
7	Methylguanidine (2.81)	Threonine (3.58)
8	Methylhistidine (3.70)	Homocysteine (3.86)
9	Cholesterol (0.91)	Glycine (3.55)
10	Taurine (3.42)	Taurine (3.42)
11	Threonine (3.58)	Methylxanthine (3.49)
12	Fatty acids (0.8–0.84, 2.22–2.24)	Choline (3.20, 3.22, 3.23)
13	Methylxanthine (3.49)	Methylhistidine (3.70)
14	Homocysteine (3.86)	Cholesterol (0.91)

* Metabolites were identified using the partial least-squares regression analysis model and represent the regions of the spectra which had the greatest influence on the correlation with C-reactive protein (CRP) level. Values in parentheses are the nuclear magnetic resonance chemical shifts (in parts per million), which identify the location of the major peaks in the spectra. LDL = low-density lipoprotein.

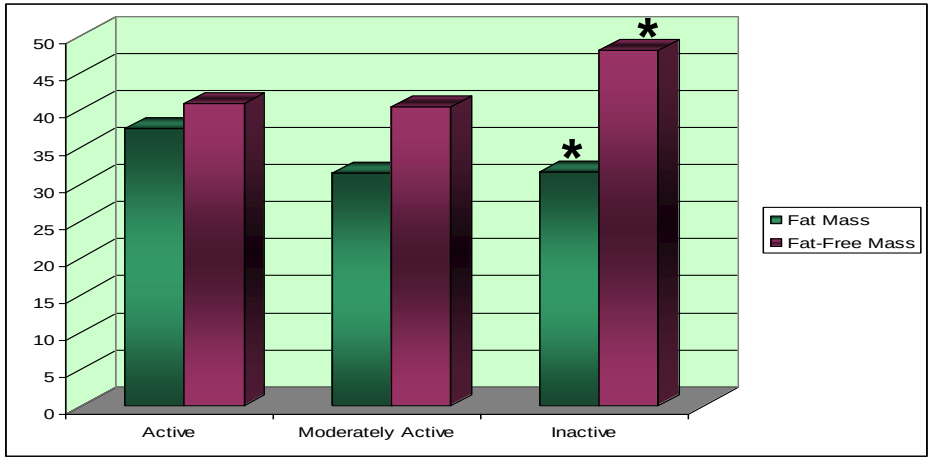
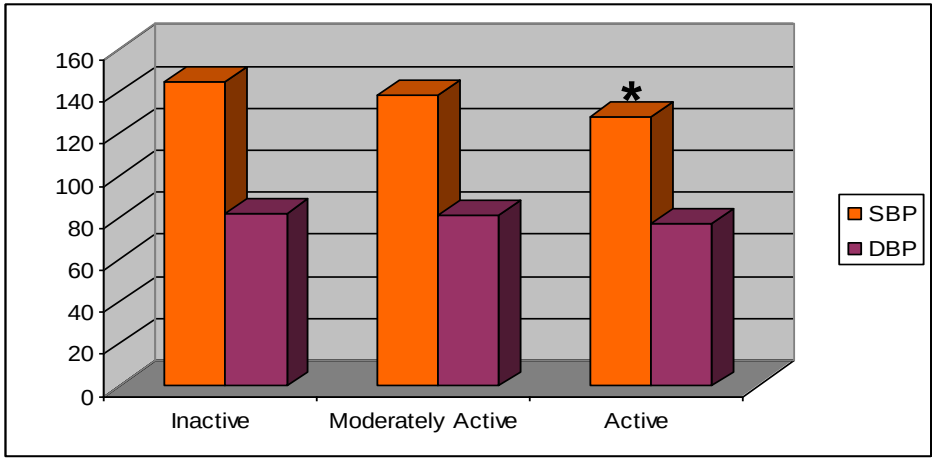
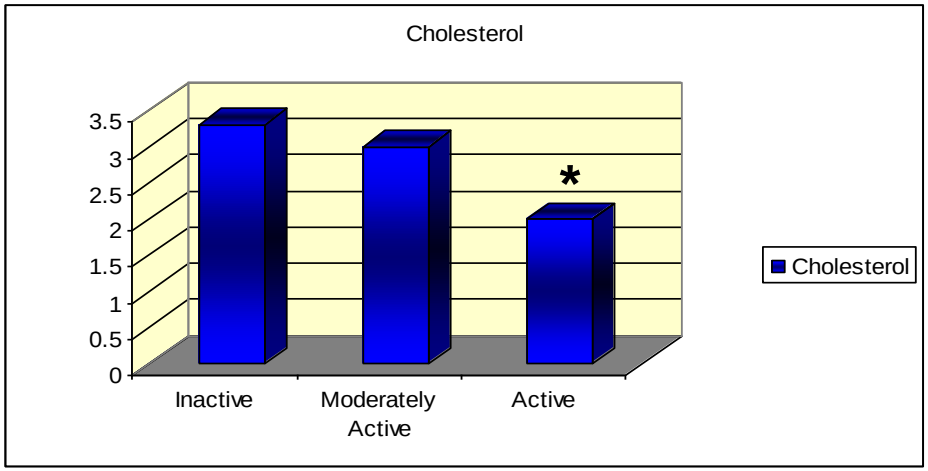
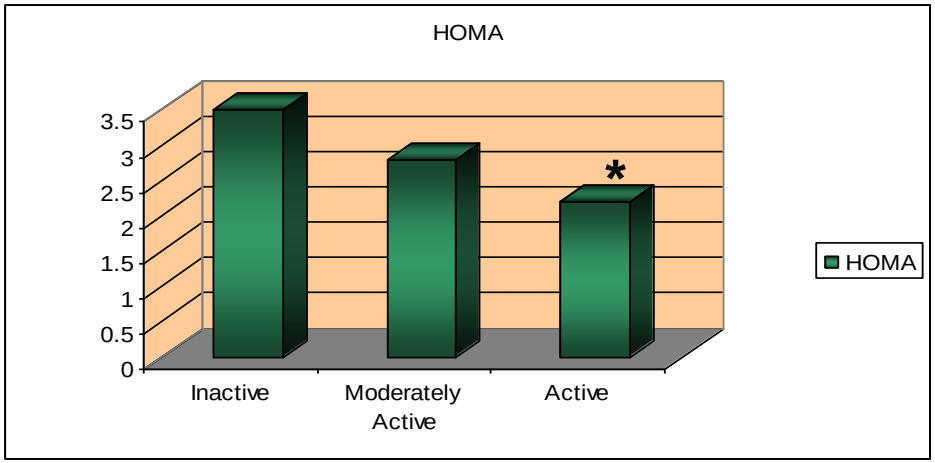
European Journal of Cardiovascular Prevention and Rehabilitation, 16(2):188-94







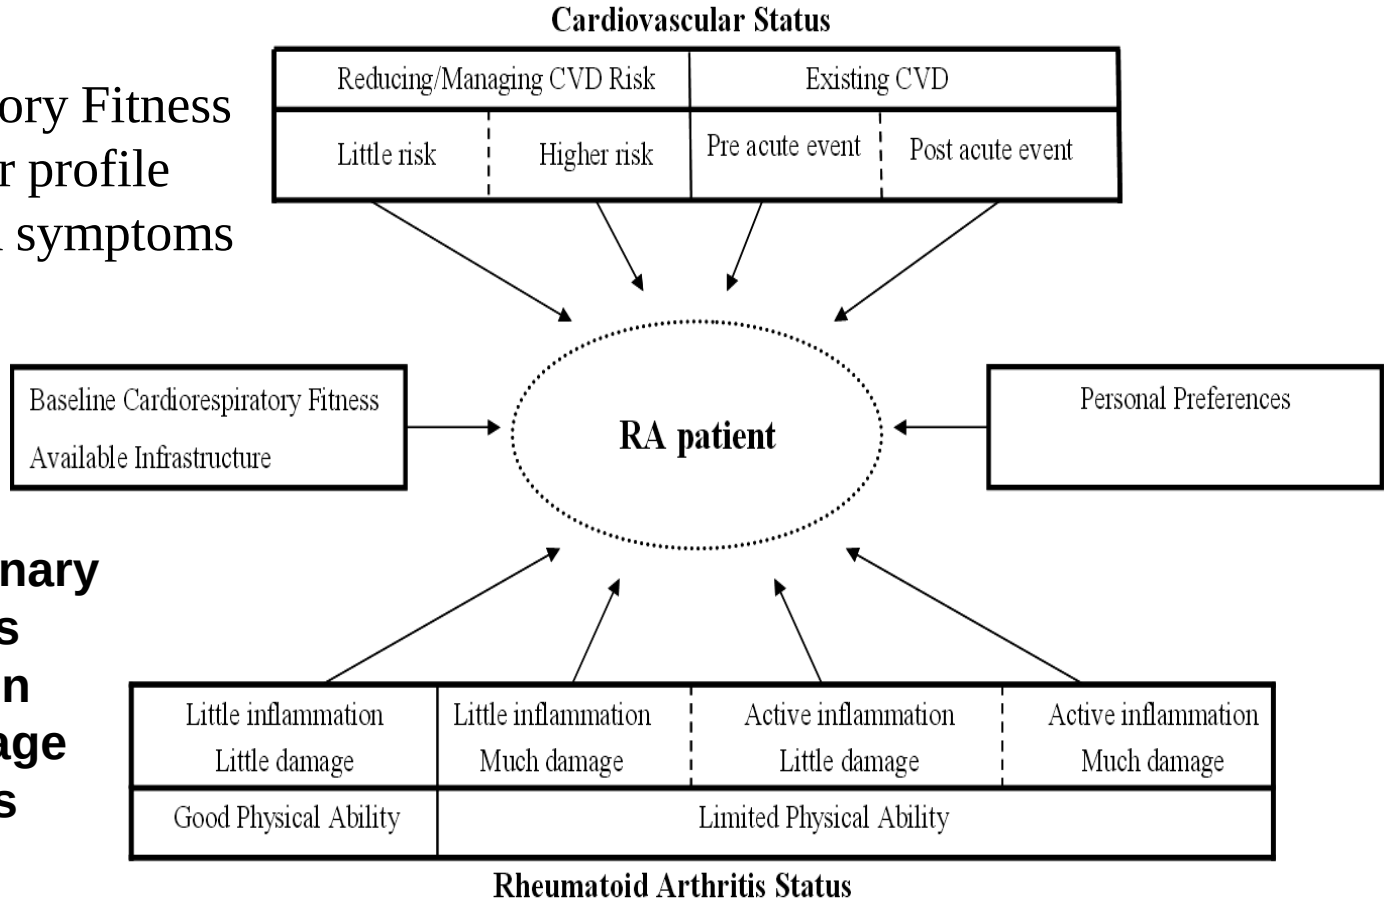


CRP significantly higher in physically inactive patients

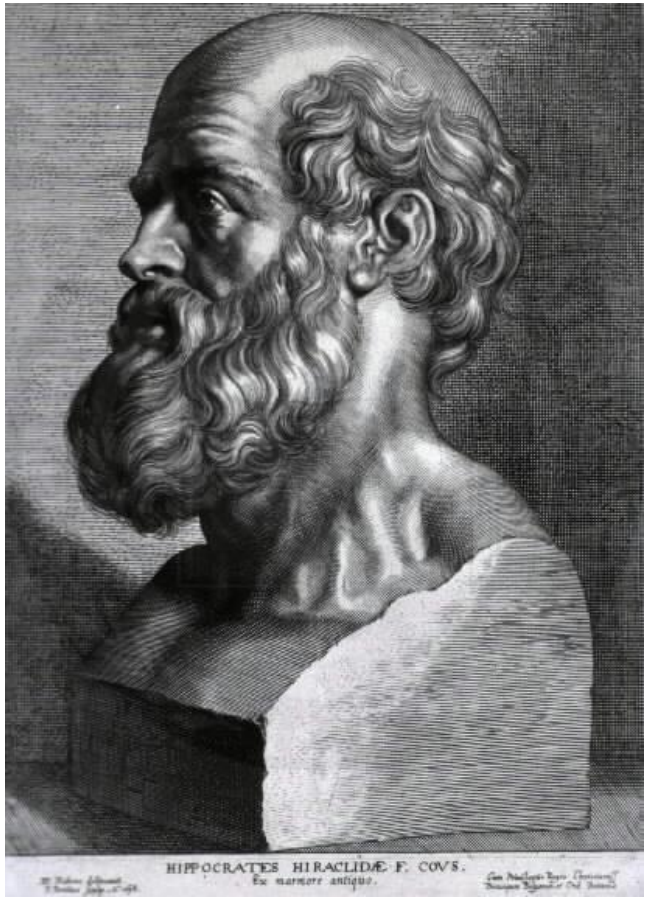
Summary – Physical Inactivity in RA

- RA patients have much lower than the recommended levels of physical activity
- However, they CAN and SHOULD exercise with the following benefits:

↑ Cardio-respiratory Fitness
↑ Cardio-vascular profile
↓ Disease-related symptoms



A multidisciplinary approach is necessary in order to engage RA patients



If we could give every individual the right amount of nourishment and exercise, not too little and not too much, we would have found the safest way to health.

Eating alone will not keep a man well; he must also take exercise. For food and exercise, while possessing opposite qualities, yet work together to produce health.

Regimen, in *Hippocrates*, trans. W. H. S. Jones (1931), Vol. 4, 229

What is the evidence for (accelerated) atherosclerosis in RA?

- Theory: the role of inflammation
- Vascular function and morphology studies - biomarkers
  (sub-clinical atherosclerosis)
- Vascular work + Epidemiology: **RA = DM type 2**
  (DM type 2 = CHD equivalent)
- Abundance of classical and novel risk factors
  - Hypertension
  - Dyslipidaemia
  - Obesity – Cachexia – Insulin resistance
  - Physical Inactivity
  - Multiple other factors (e.g. drugs, smoking, RhF etc.)

RA treatment effects on CVD risk factors

• NSAIDs / Coxibs	Hypertension
• Hydroxychloroquine	↓ Lipids, DM
• Methotrexate	↓ Met. Syndrome ↑ Homocysteine
• Steroids	Hypertension Dyslipidaemia Insulin resistance
• Biologics	Lipids, BP Body composition

Abstract

OBJECTIVE:

RA is associated with increased cardiovascular events, reportedly to equal diabetes mellitus (DM). The presence of myocardial ischaemia was assessed in asymptomatic high-risk RA patients and compared with patients with DM and a healthy control group.

METHODS:

Eighteen consecutive non-diabetic RA patients without known cardiovascular disease who developed a new carotid atheromatic plaque during the last 3 years were matched 1:1 for traditional cardiovascular risk factors with asymptomatic type 2 DM patients and 1:2 with asymptomatic non-RA, non-DM control subjects. After dobutamine stress contrast echocardiography with wall-motion and perfusion evaluation, coronary angiography was performed in those with positive stress tests.

RESULTS:

Ischaemia by echocardiography was found in 67% of RA patients; this was significantly higher than controls (31%, P = 0.019) but comparable to those with DM (78%, P = 0.71). Angiography performed in eight consenting RA patients was normal in four, revealed non-flow-limiting coronary atheromatic lesions in two and significant lesions in two patients. RA patients with ischaemia had CRP serum levels significantly higher by six-fold compared with those with normal stress echocardiography.

CONCLUSION:

Asymptomatic RA patients may display myocardial ischaemia at similar levels to DM patients but with low prevalence of obstructive coronary artery disease. Microvascular abnormalities associated with increased inflammatory response may account for these findings. Their exact nature and significance require further evaluation.

What is the evidence for **microvascular** disease / dysfunction in RA?

- Disease phenotype: rheumatoid vasculitis
- Thallium scans
- Stress contrast echo – coronary angiography
- CMR

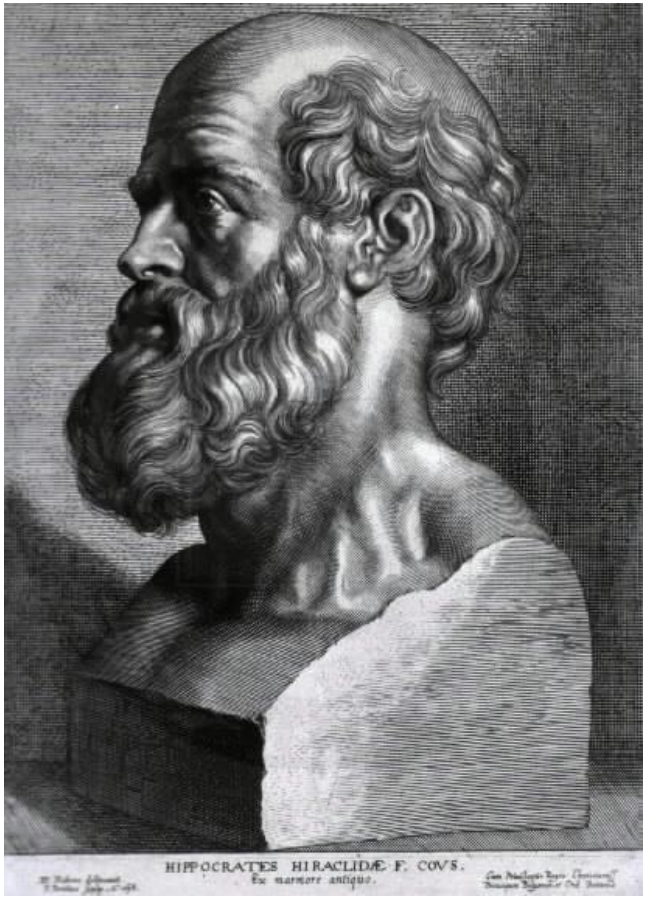
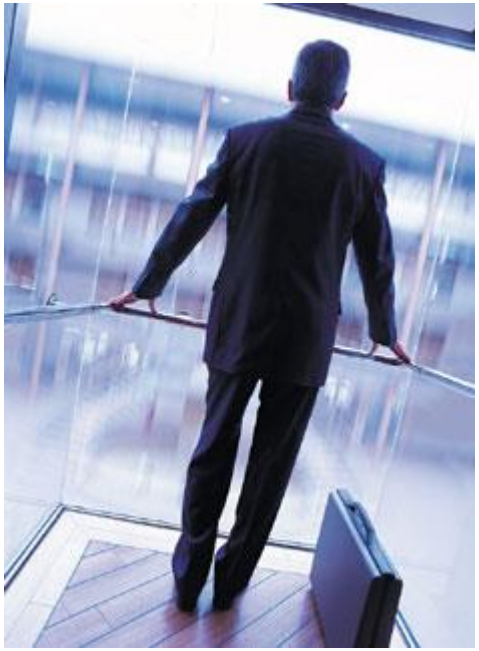
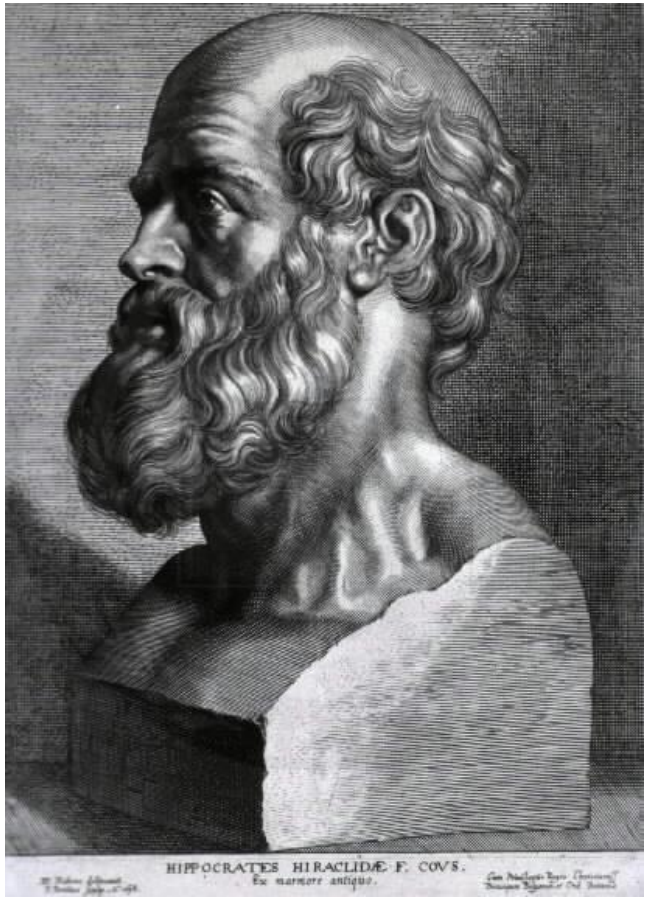
- What is the problem?
- What is the nature of the problem?
  - (Accelerated) Atherosclerosis?
  - Plaque instability?
  - Other mechanisms?
- **Summary**



"the <u>patient</u> should be the focus of care"





There are in fact two things, science and opinion; the former begets knowledge, the latter ignorance.

— Hippocrates

Law sect. 4, in *Hippocrates*, trans. W. H. S. Jones (1923), Vol. 2, 265.

Summary

- CVD is remains an important co-morbidity in RA – but is it as important for mortality as in the past?
- There is some evidence for accelerated atherosclerosis
  - Driven mostly by classical risk factors
  - Aggressive identification is required
  - Optimal management for RA still unknown
- There is good evidence for plaque instability
  - Driven mostly by inflammatory mechanisms
  - Aggressive suppression of inflammation may be helping here
- The importance of processes other than atherosclerosis, particularly microvascular disease, is re-emerging and needs a lot of investigation in terms of pathogenesis, clinical importance and relevance to outcome.
- Specifically designed clinical trials are needed but are very challenging and may require international collaborations

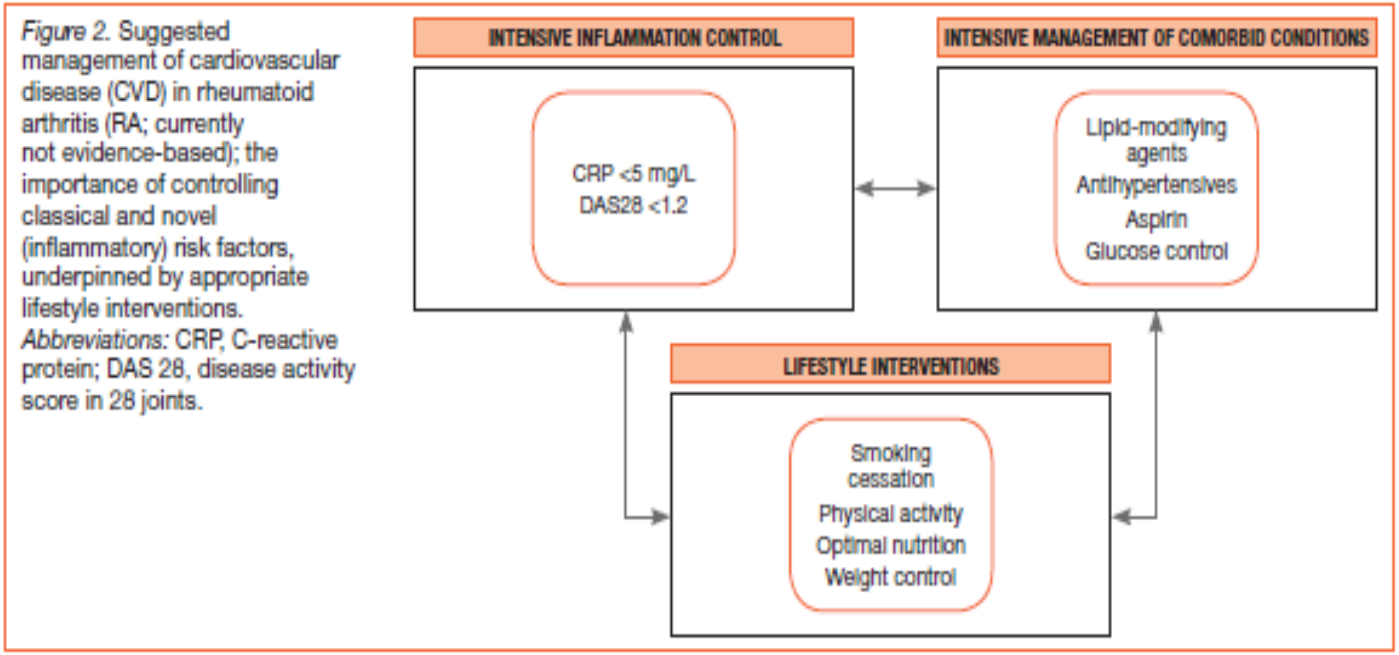


Figure 2. Suggested management of cardiovascular disease (CVD) in rheumatoid arthritis (RA; currently not evidence-based); the importance of controlling classical and novel (inflammatory) risk factors, underpinned by appropriate lifestyle interventions. *Abbreviations:* CRP, C-reactive protein; DAS 28, disease activity score in 28 joints.

A practical approach

- Address system failures
- Address the INDIVIDUAL patient
- Use knowledge from other disease entities
- Facilitate the generation of RA-specific evidence through research

- **Use common sense**
